In this paper we refer to a 1.2 mm measurement of HD 100453 and quote a flux of 30 mJy. This flux is incorrect. The correct value obtained in the measurement is 265 ± 21 mJy (S. Wolf and M. Albrecht, private communication). When considering this value, the long wavelength slope α of the SED

is now -2.8 instead of -3.7 . The new value is consistent with large grains. Therefore, the general lack of small silicate grains is the most likely explanation for the weakness of the 10 μm silicate feature in this source. We are grateful to M. Albrecht for reducing and discussing the SIMBA data.
